ABSTRACT
Seaweeds are known to contain a wide variety of chemical compounds, many of the compounds have commercial applications in pharmaceutical, medical, cosmetic, nutraceutical, food and agricultural industries. In the present study, the screening of diuretic activity of Chaetomorpha litorea Harvey collected from Koothankuzhi coast in the south east coast of Tamil Nadu, India was analyzed. Dry powdered plant materials were subjected to methanol extract at the dose of 200mg/kg and 400mg/kg body weight. Methanol crude extract showed potential significant diuretic activity in both doses from 1 hour to 4 hour as compared to the standard drug furosemide. The results showed for the first time that Chaetomorpha litorea Harvey exhibited significant diuretic activity, a property that could lead to the application in one of many useful healthcare or related products as well as in chemoprevention of the diseases.

INTRODUCTION
Seaweeds have been widely used by coastal populations for thousands of years owing to the high nutritional values [1]. Seaweeds are found to be very rich sources of food, feed, medicines and energy. Moreover, seaweeds are the only sources for industrially important phycocolloids like agar, carrageenan and alginate. They have a lot of applications as stabilizer, viscosifier, gelling and emulsifying agents [2]. Apart from industrial uses, in recent years, polysaccharides of plant origin have emerged as an important class of bioactive natural products [3]. Nature has been a source of medicinal agents for thousands of years and an impressive number of modern drugs have been isolated from natural sources, many of these isolations were based on the uses of the agents in traditional medicine [4].

Diuretics are the drugs that increase the rate of urine flow, sodium excretion and are used to adjust the volume and composition of body fluids in a variety of clinical situations. Drug-induced diuresis is beneficial in many life-threatening disease conditions such as congestive heart failure, nephritic syndrome, cirrhosis, renal failure, hypertension, and pregnancy toxemia. Most diuretic drugs have the adverse effect on quality of life including impotence, fatigue, and weakness. Naturally occurring diuretics include caffeine in coffee, tea, and cola, which inhibit Na+ reabsorption and alcohol in beer, wine inhibit secretion of ADH although most of the diuretics proved to be very effective in promoting sodium excretion, all cause potassium loss and prompted the search for potassium sparing diuretic. Hence search for a new diuretic agent that retains therapeutic efficacy and yet devoid of potassium loss is justified.

Thus, medical and pharmaceutical industries are also interested since seaweeds have proven to be rich sources of structurally diverse bioactive compounds with valuable pharmaceutical and biomedical potential [5]. Indeed, the complex polysaccharides from seaweeds...
especially possess broad spectrum therapeutic properties and are reported to exhibit blood anticoagulant [6], immunomodulating, antitumor [7], antiviral [8] and antioxidant activities [9]. Hence the present investigation was designed to evaluate the diuretic activity of Chaetomorpha litorea Harvey collected from Koothankuzhi coast in the south east coast of Tamil Nadu, India.

MATERIALS AND METHODS

Collection of Plant Sample

Chaetomorpha litorea Harvey (Figure 1) is green seaweed belonging to Chlorophyceae member showed much attention in the present study for diuretic activity. Chaetomorpha litorea Harvey were collected from Koothankuzhi, in the south east coast of Tamil Nadu, India during the month of July 2014. The collected plant samples were rinsed with marine water to remove debris and epiphytes. The entire epiphytes were removed using soft brush. The plants were brought to the laboratory. In the laboratory, the plants were once again washed in freshwater and stored in refrigerator for further analysis [10].

Preparation of methanol extract

For the preparation of methanol extract of Chaetomorpha litorea Harvey, the collected plant specimens were washed thoroughly and placed on blotting paper and spread out at room temperature in the shade condition for drying. The shade dried samples were grounded to fine powder using a tissue blender. The powdered samples were then stored in the refrigerator for further use. 3g powdered sample was packed in Soxhlet apparatus and extracted with methanol for 8h separately. The excess amount of methanol was evaporated and fine methanol crude powder was prepared and stored in the refrigerator for the antipyretic activity [11].

Experimental Animals

Wistar albino rats (160-200g) and Swiss albino mice of either sex were procured from Venkateswara Enterprises, Bangalore, Karnataka, India. The selected animals were acclimatized for 7 days under standard husbandry conditions, i.e. room temperature 35±1°C, relative humidity 45-55% and light/dark cycle 12/12h. Animals were provided with standard rodent pellet diet and had free excess to water. The composition of diet is 10% protein, 4% Arachis oil, 1% fibers, 1% calcium, 1000 IU/gm vitamin A and 500 IU/gm vitamin D. All the animals were acclimatized to the laboratory conditions prior to experimentation. All the experiments were conduct between 10.00 and 17.00h and were in accordance with the ethical guidelines of the International Association for Study of Pain [12]. All experiments were carried out according to the guidelines for care and use of experimental animals and approved by Committee for the Purpose of Control and Supervision of Experiments on Animals (CPCSEA).

Acute toxicity test

Acute oral toxicity study was performed as per OECD-423 guidelines [13]. Albino mice (n=6) of either sex selected through random sampling technique was used for acute toxicity study. The animals were kept fasting for overnight providing only water, after which the extract (50% methanolic extract) was administered orally at the dose level of 5 mg/Kg body weight by gastric intubation and observed for 14 days. If mortality is observed in 2 out of 3 animals, then the dose administered would be assigned as toxic dose. If mortality is observed in 1 animal, then the same dose would be repeated again to confirm the toxic dose. If mortality is not observed, the procedure would be repeated for further higher doses such as 50, 300 and 2000 mg/Kg body weight. According to the results of acute toxicity test, the doses were chosen for experiments.

Diuretic activity

The method described Wiebelhaus et al. [14] was employed with modification for the assessment of diuretic activity. Healthy albino rats of either sex (160-200g) were divided into four groups of six animals each. They were fasted 18h prior to the test with free access to water. On the day of the experiment, Group I animals were given 5ml/Kg of body weight normal saline orally and served as control group. Groups II, III and IV were treated with standard drug (Furosemide 5mg/Kg p.o.), methanolic crude extract (200mg/Kg) and methanolic crude extract (400mg/Kg) respectively. Standard drug and crude extracts were administered orally (p.o.). Immediately after dosing, the rats were placed in the metabolic cages with special provision to collect faeces and urine. Animals were kept at room temperature of 35±1°C throughout the experiment. Urine excreted for the next 4h from 15min was collected and the total 4h urine volume for each rat was compared with the volume of urine produced after the administration of normal saline. The volume of urine excreted during 4h for each animal in the group was expressed as the percent of the liquid (normal saline) administered. This percentage gave a measure of urinary excretion independent of the animal weight. The ratio of urinary excretion in the test group to urinary excretion in the control group was used as a measure of the diuretic action for the given dose of the drug. The diuretic activity of the crude extract was compared to that of the standard drug in the test group [15]. The parameters taken to study were pH, Na+, K+ and Cl− concentration in urine. Urine samples were analyzed thereafter for pH by pH meter, Na+ and K+ concentration by flame photometric method while Cl− concentration will be determined titrimetrically and the results were reported as mean ± SEM.

Statistical analysis

The data were expressed as mean ± SEM. The data
of diuretic activity were analyzed by one-way analysis of variance (ANOVA) followed by “Dunnett’s test.” p-value < 0.05 was considered statistically significant.

RESULTS AND DISCUSSION

Screening of diuretic activity of methanol crude extract of Chaetomorpha litorea Harvey was studied by determining the effect on albino rats. The methanol extract of Chaetomorpha litorea Harvey showed the highest obvious diuretic activities which was dose dependent on albino rats. Acute toxicity studies showed that the methanolic extracts did not cause any mortality up to 2000mg/Kg and were considered as safe [16]. The present study examined the diuretic potential of Chaetomorpha litorea Harvey.

The results showed that both the methanol crude extracts (200mg/kg and 400mg/kg) increased urine output up to 4h following its administration which compared to control group (Table I). The amount of urine collected from standard fruosemide (group II), 200mg/kg methanol crude extract (group III) and 400mg/kg methanol crude extract (group IV) was found to be 6.95ml, 9.2ml and 2.7ml respectively as compared with control (group I) as presented in Figure 2. Diuretic activity of 200mg/kg methanol crude extract was found to be highest compared to 400mg/kg methanol crude extract in the present study.

Table 1 showed the urinary electrolyte content following the administration of the methanol crude extracts. The dose of 200mg/kg methanol crude extract produced a significant increase in Na⁺ (from 76.30meq/L to 112.34meq/L), K⁺ (from 48.54meq/L to 74.89meq/L), Cl⁻ (from 82.63meq/L to 80.48meq/L) excretion and pH showed a small change from 6.5 to 6.4 compared with the Standard drug Fruosemide (5mg/kg p.o.). The dose of 400mg/kg methanol crude extract produced a significant decrease in the Na⁺ (from 128.32meq/L to 81.75meq/L), K⁺ (from 78.87meq/L to 52.32meq/L) Cl⁻ (from 84.22meq/L to 75.82meq/L) excretion and pH showed decreased state from 7.1 to 6.3 compared with control group (Figure 3).

However, 200 mg/kg of the methanol crude extract produced a significant decrease in Na⁺ from 128.32meq/L to 112.34meq/L, K⁺ from 78.87meq/L to 74.89meq/L, Cl⁻ from 82.63meq/L to 80.48meq/L excretion and pH showed a small change from 6.5 to 6.4 compared with the standard drug Fruosemide (5mg/kg p.o.). The dose of 400mg/kg methanol crude extract produced a significant decrease in the Na⁺ (from 128.32meq/L to 81.75meq/L), K⁺ (from 78.87meq/L to 52.32meq/L) excretion and pH from 6.5 to 6.3 compared with Standard drug Fruosemide (5mg/kg p.o.).

In the present study, methanol crude extract of Chaetomorpha litorea Harvey affected urinary electrolyte. Both the methanol extracts (200mg/kg and 400mg/kg) were not accompanied with reduction in urinary K⁺ level. In addition there was no alkalization of urine. These data indicate that they were not acting as potassium sparing diuretics [17, 18]. The methanol crude extract was unlikely to be acting as thiazide diuretics. Thiazide only increase urinary K⁺ level and alter the urinary Na⁺/K⁺ ratio. But in the present study both urinary Na⁺ and K⁺ level were increased without any alteration in Na⁺/K⁺ ratio. The diuresis induced by methanolic crude extract of Chaetomorpha litorea Harvey was similar to that of furosemide and accompanied by marked increases in both urinary Na⁺ and K⁺ level. Further the urine was slightly acidified. These characteristics strongly suggested that the methanol crude extract was acting as loop diuretic. Loop diuretics inhibit the Na⁺, K⁺, and Cl⁻ co-transporter system in the thick ascending loop of nephrion, thereby increasing natriuresis and kaliuresis and also cause acidification of urine.

CONCLUSION

From the results, it can be concluded that the methanolic crude extract of *Chaetomorpha litorea* Harvey possess significant diuretic activity by increasing the total urine output and increased excretion the total Sodium, Potassium and Chloride levels. However, the activity was dose dependent. At 200mg/kg methanol crude extract was highly effective than 400mg/kg methanolic crude extract and the standard drug furosemide. Hence, the isolation of active principles will be advantageous to produce novel bioactive constituents from methanol crude extract of *Chaetomorpha litorea* Harvey which may possess more significant for diuretic activity.
