ABSTRACT

Today indiscriminate and uncontrolled discharge of metal contaminated industrial effluents into the environment has become an issue of major concern. Release of heavy metal without proper treatment poses a significant threat to public health because of its persistence biomagnifications and accumulation in food chain. To reduce metal pollution problems many processes have been developed for the treatment and disposal of metal containing wastes. The major shortcomings of the conventional treatments & low efficiency at low concentration of heavy metals, expensive handling and safe disposal of toxic sludge. Microbial metal bioremediation is an efficient strategy due to its low cost, high efficiency and ecofriendly nature moreover it results in the partial or complete biotransformation of wastes to microbial biomass and stable end products. In present work, coloration, Biological Oxygen Demand (BOD), Chemical Oxygen Demand (COD), turbidity, TS, TDS, TSS, Optimization of effluent and heavy metal (Nickel, Chromium) removal from electroplating industrial effluent by microorganisms such as *Bacillus sp.*, *Micrococcus sp.* and *Microbacterium sp.* were studied and analysis suggested that three strains are better microbial tool for bioremediation of heavy metal. Hence possibility can be explored to remove heavy metal load, present even in low concentration, in waste water of electroplating industrial effluent by using microorganisms.

INTRODUCTION

The growing industrialization and modern agricultural practices that have spread worldwide are adversely affected the ecosystem. These practices have leave persistent toxic metals and organic pollutants in the surroundings which tend to accumulate and deteriorate the environment [1]. Contamination of heavy metals in the environment is a major global concern because of their toxicity and threat to human life and environment. Much research work has been carried out on heavy metal contamination in soils from various anthropogenic sources such as industrial wastes, automobile emissions, mining

activity and agricultural practices. Bioremediation has evolved as the most promising one because of its economical, safety and environmental features. Since organic contaminants become actually transfer and some of them are fully mineralized [2]. This method is at least six times cheaper than incineration and three times cheaper than confinement. An Incorporation of Nickel in 4 microbial enzymes involved in Ureolysis, Hydrogen metabolism, methane synthesis and acetogenesis [3]. Chromium is useful in Tanning, Paints, Pigment and fungicide industry and effect of Nephritis, cancer and ulceration [4]. Microbes for metal remediation mechanisms by which metal ions bind to the cell surface include electrostatic interactions, Van der Waals forces, covalent bonding, redox interactions and extracellular precipitation (or) a combination of these processes [5].

MATERIALS AND METHODS

Sampling site and isolation of microorganisms from the effluent:

The bacteria were isolated from electroplating industry. The samples were collected in the plastic cans and brought to the analytical laboratory for bioremediation studies. The efficient sample 1ml was suspended in 99ml of the sterile saline solution and was thoroughly mixed with a vortex after separating of 100 ml of each suspension on nutrient agar (NA). The sample was aerobically incubated for 3 day at 37⁰C. After incubation , colonies were selected for isolation. *Bacillus sp*, *Micrococcus sp* and *Microbacterium sp* isolates were picked up and purified by repeated streaking on.

Identification of isolates:

For the identification of the isolates morphological and some biochemical properties of the isolates were determined by carrying out the gram staining, catalase test in accordance with Bergey's manual of systemic bacteriology [6].

Acclimatization of the culture

The isolated bacterial species were acclimatized in NiSO₄ and K₂Cr₂O₇ salt. Then allowed to grow at 1g/10ml concentration of Ni, Cr in broth for 24 hrs.

Estimation of Initial metal level in the effluent:

1ml of effluent was taken as a sample and the amount of nickel and chromium was estimated by using the standard method and the initial amount of metals were calculated by calibrating the concentration against the standard graph.

Analysis of Sample:

pH was recorded and further analyzed in the laboratory for their physiochemical characteristics like coloration, turbidity, TSS, BOD, COD by standard methods of APHA [7].

Optimization of Media:

The medium were prepared according the Plackette – Burmann design [8] for each trail of appropriate high and low concentration. Through this (high and low) variants, the medium prepared and used for the Plackette – Burmann method optimization.

Statistical Analysis: Analysis of Varinace (ANNOVA)

ANNOVA is the systematic procedure for the analysis of variation. It consists of classifying and cross – classifying statistical results and testing whether the means of specific classification differ significantly. It is used to

test the significance of the difference among sample means.

RESULT AND DISCUSSION

The removal of toxic metals such as Chromium and Nickel from the dilute solutions resulting from electroplating industry. The industrial effluents cause soil and groundwater pollution besides causing a number of adverse effect on plants, animal and human health. Due to awareness of the adverse ecological effects of toxic metals, several investigation advocate appropriate techniques for the different techniques implied in the treatment of the industrial wastes before being discharged out is the use of bacteria for the removal of metal ions from effluent which offers great potential. *Bacillus sp*, *Micrococcus sp* and *Microbacterium sp* plays a vital role in bioremediation studies. They easily acclimatize to any environment and shows their maximum growth efficiency from the effluents microbiological analysis was subjected and the isolates were *Bacillus sp.*, *Micrococcus sp.*, *Microbacterium sp.*

Then, the physiochemical character (BOD, COD, TDS, TSS, pH, Temperature) of the effluents were done by Dr. Rajan method. These physiochemical characters were measured to know the effect of the effluent. The effect of the effluent was calculated and denoted in Table. 1.

The biodegradation of chromium and nickel is run by minimal salt medium inoculated with *Bacillus sp*, *Micrococcus sp* and *Microbacterium sp* of various concentration and time intervals of each tubes respectively. The level of biodegradation of chromium and nickel were analysed in 6 days intervals. The highly biodegradable strains were *Bacillus sp*, *Micrococcus sp* and *Microbacterium sp* in chromium upto 95%, 93% and 95% at 5th day (Table 2, figure – 1)

Then, these highly biodegradable strains were *Bacillus sp*, *Micrococcus sp* and *Microbacterium sp* in nickel upto 94%, 94% and 97% at 5th day.

The highly biodegradable strains were *Bacillus sp*, *Micrococcus sp* and *Microbacterium sp* were selected for the optimization studies. Medium optimization was done by Plackette – burmann design. The effective degradation of nickel and chromium was done at trails 1 to trails 8, with the high and low amount of pH, temperature, glucose and yeast extract were shown in Table 3.

The highly degradation of chromium was done at trial 4 in *Bacillus sp*, trail 5 in *Micrococcus sp*, trail 8 in *Microbacterium sp* and percentage are 98%, 98%, 97%. (Table 4-9, Fig 2-7).

For statistical analysis, the respective totals were calculated between and within sample. Grand total was arrived by summing the total of different metal degradable microbes.

Table 1. Characteristics of the Effluent

| S.NO | Characteristics | Sample 1 | Sample 2 |
|------|------------------------|------------------|------------------|
| 1 | pH | 5.80 | 2.92 |
| 2 | Temperature | 28°C | 30°C |

CONCLUSION

Remediation of metal contaminated soil and water is a necessity in order to have a safe and healthy environment that will in turn results in healthy style across the globe. Biological remediation of metal contaminated soil and water offers a better and more eco- friendly technique that if properly and thoroughly explored can bring our environment into a better place for both plant and animals well being to its enormous advantages over other treatment methods.

Future research and development will requires focus on the use of cheap, eco- friendly and widely available nutrients that can be used to enhance the microbial and plant activities in mineralizing hydrocarbons and heavy metals in soil and water environment.

Metal degrading bacterial strains were isolated from waste disposable site. That microbial strain were subjected and it was identified as the bacterial strains were identified as the bacterial strains were *Bacillus sp*, *Micrococcus sp* and *Microbacterium sp* confirmed family

by Bergey's manual of systemic bacteriology. The BOD, COD, TS, TDS, TSS, pH, Temperature, Color, Turbidity and metals of the effluents were identified. The biodegradation of metal done by minimal salt medium which was supplement with microbial strains were *Bacillus sp*, *Micrococcus sp*, and *Microbacterium sp* were effectively degraded Chromium and Nickel.

Then, the optimization studies were followed by the Plackette RL and Burmann JP design and 3 different strains of *Bacillus sp*, *Micrococcus sp* and *Microbacterium sp* were Chromium and Nickel.

ANNOVA results confirm that 3 different strains of *Bacillus sp*, *Micrococcus sp* and *Microbacterium sp* were degraded the Chromium and Nickel metals.
