INTRODUCTION

The dorsalis pedis artery also called as arteria dorsalis pedis is the continuation of the anterior tibial artery, passes forward from the ankle-joint along the tibial side of the dorsum of the foot to the proximal part of the first intermetatarsal space, where it divides into two branches, the first dorsal metatarsal and the deep plantar arteries. The dorsal artery of the foot may be larger than usual, to compensate for a deficient plantar artery; or its terminal branches to the toes may be absent, the toes then being supplied by the medial plantar; or its place may be taken altogether by a large perforating branch of the peroneal artery. This artery frequently curves laterally between the middle of the ankle and the back part of the first interosseous space. The branches of the dorsalis pedis artery are the lateral tarsal, arcuate, medial tarsal, first dorsal metatarsal and deep plantar arteries. The lateral tarsal artery arises from the dorsalis pedis, as that vessel

crosses the navicular bone; it passes in an arched direction laterally, lying upon the tarsal bones, and covered by the extensor digitorum brevis; it supplies this muscle and the articulations of the tarsus, and anastomoses with branches of the arcuate, anterior lateral malleolar and lateral plantar arteries, and with the perforating branch of the peroneal artery. The medial tarsal arteries are two or three small branches which ramify on the medial border of the foot and join the medial malleolar network. The arcuate artery arises a little anterior to the lateral tarsal artery; it passes laterally, over the bases of the metatarsal bones, beneath the tendons of the extensor digitorum brevis, its direction being influenced by its point of origin; and its anastomoses with the lateral tarsal and lateral plantar arteries. This vessel gives off the second, third, and fourth dorsal metatarsal arteries, which run forward upon the corresponding dorsal Interossei; in the clefts between the

toes, each divides into two dorsal digital branches for the adjoining toes [1]. At the proximal parts of the interosseous spaces these vessels receive the posterior perforating branches from the plantar arch, and at the distal parts of the spaces they are joined by the anterior perforating branches, from the plantar metatarsal arteries. The fourth dorsal metatarsal artery gives off a branch which supplies the lateral side of the fifth toe. The first dorsal metatarsal artery runs forward on the first Interosseous dorsalis, and at the cleft between the first and second toes divides into two branches, one of which passes beneath the tendon of the extensor hallucis longus, and is distributed to the medial border of the great toe; the other bifurcates to supply the adjoining sides of the great and second toes. The deep plantar artery descends into the sole of the foot, between the two heads of the first interosseous dorsalis, and unites with the termination of the lateral plantar artery, to complete the plantar arch. It sends a branch along the medial side of the great toe, and is continued forward along the first interosseous space as the first plantar metatarsal artery, which bifurcates for supplying the adjacent sides of the great and second toes [2].

CASE REPORT

During routine dissection, of the lower limb of a 70 year old donated embalmed male cadaver in the Department of Anatomy, K.J. Somaiya Medical College, Sion, Mumbai, India, I observed two dorsalis pedis arteries arising from the anterior tibial artery on the right upper limb. The anterior tibial artery divided into two dorsalis pedis arteries in the lower part of the leg. Both the arteries travelled together on the dorsum of the foot up to the proximal part of the first intermetatarsal space. The anterior tibial artery was exposed through a longitudinal incision in lateral calf over the mid portion of anterior compartment. The tibialis anterior and extensor hallucis longus muscles were fused, and neurovascular bundle was exposed between these and the extensor digitorum muscle; The anterior tibial artery, its paired tibial veins, and the tibial nerve were dissected along the surface of the interosseous membrane and the two dorsalis pedis arteries were observed. The pattern of nerves in the leg was normal. The variation was unilateral. The photographs of the double dorsalis pedis arteries were taken for proper documentation.

DISCUSSION

In humans, the dorsalis pedis artery (dorsal artery of foot), is a blood vessel of the lower limb that carries oxygenated blood to the dorsum of the foot. It arises at the anterior aspect of the ankle joint and is a continuation of the anterior tibial artery. It terminates at the proximal part of the first intermetatarsal space, where it divides into two branches, the first dorsal metatarsal artery and the deep plantar artery. Along its course, it is accompanied by a deep vein, the dorsalis pedis vein. In the foot it gives off medial and lateral tarsal arteries, arcuate artery and first dorsal metatarsal artery. The dorsalis pedis artery pulse can be palpated readily lateral to the extensor hallucis longus tendon (or medially to the extensor digitorum longus tendon) on the dorsal surface of the foot, distal to the dorsal most prominence of the navicular bone which serves as a reliable landmark for palpation [3]. It is often examined, by physicians, when assessing whether a given patient has peripheral vascular disease. It is absent, unilaterally or bilaterally, in 2-3 % of young healthy

individuals. A number of anomalies of the dorsalis pedis artery have been noted by the anatomists and surgeons. The dorsalis pedis artery has been found to arise from the perforating branch of peroneal artery. The dorsalis pedis artery divided into two terminal branches 3cm distal to its origin. The dorsalis pedis artery was the continuation of peroneal artery found in around 8% of the cases [4,5].

In the present study two dorsalis pedis arteries were seen arising from the anterior tibial artery. Both the arteries ran together side by side to reach the first intermetatarsal space, The dorsalis pedis artery – 1, dipped in the proximal aspect of the space and the dorsalis pedis artery – 2, continued as 1st dorsal metatarsal artery. The aberrant arteries or anomalous course of the arteries of the lower limb can be attributed to their development.

Developmental Basis

The axis artery of the lower limb develops from the 5th lumbar intersegmental artery. The embryonic blood

vessels acquire a plexiform appearance in the foot. The dorsalis pedis artery is a constant embryonic vessel that plays an important role in the normal arterial morphogenesis of the lower limb. The tiny blood vessels derived from the blood islands in the 3rd and 4th week of development merge with each other forming a continuous network of fine vessels. New vessels buds out from the walls grow out and get canalized to form newer vessels. These newer vessels of the neighbouring areas join to form a closed network. The adult arterial pattern of the lower limb develops from multiple and plexiform sources of vessels, and emergence of anastomoses between these vessels, which is followed by regression of some channels depending on the functional dominance. This explains why the anomalies of the blood vessels of the limbs not only present as divergence in the origin and course but also as supernumerary vessels in the region [6].

Clinical significance

The knowledge of any variation in the course and distribution of the dorsalis pedis artery is clinically important because the dorsalis pedis artery is used to record peripheral arterial pulsation. Since the dorsalis pedis artery serves as an important pedicle for most of the reconstructive surgeries of the foot, the knowledge about the aberration of the usual anatomic pattern of origin, branching and anastomosing patterns of the artery are of prime importance to the general surgeons, orthopedic surgeons, plastic and reconstructive surgeons who deal with this area [7]. The change in lifestyle in this 21st century has increased the number of diabetic patients. Long standing and neglected cases of Diabetes end up with

diabetic neuropathy and diabetic foot ulcers. These non-healing diabetic foot ulcers are challenging problems, for surgeons, which are commonly dealt with by musculocutaneous flaps based on the branches of dorsalis pedis artery [8].

CONCLUSION

The knowledge of double dorsalis pedis artery is clinically important for surgeons operating on non-healing diabetic foot ulcers using musculocutaneous flaps to improve blood supply and soft tissue coverage based on the branches of dorsalis pedis artery. A lack of knowledge of such type of variations might complicate surgical repair.

ACKNOWLEDGEMENT

The author is thankful to Dean Dr. Geeta Niyogi Madam for her support and also thankful to the Head of Department Dr. Sawant and all the staff members of the Department of Anatomy. The author also acknowledges the immense help received from scholars whose articles are included as references in this paper.

CONFLICT OF INTEREST

The authors declare that they have no conflict of interest.

STATEMENT OF HUMAN AND ANIMAL RIGHTS

All procedures performed in human participants were in accordance with the ethical standards of the institutional research committee and with the 1964 Helsinki declaration and its later amendments or comparable ethical standards. This article does not contain any studies with animals performed by any of the authors.
